

# Trump Harris Debate Transcript

where can i find trump harris debate transcript full

You can find the full transcript of the debate between Donald Trump and Kamala Harris on several websites. A reliable source is ABC News, which provides a detailed account of their exchanges during the debate. The transcript includes various topics discussed, including race, the economy, and their contrasting political views.

You can read the full transcript on ABC News . Other sources, like Rev, also offer transcripts if you're looking for an alternative.

The ABC news is a \*partial\* transcript

For the full transcript of the debate between Donald Trump and Kamala Harris, you can check out sources like Rev, which has an AI-generated transcript of the entire debate. Another option is the C-SPAN website, which typically archives full transcripts of debates and other political events. Here are the links to these transcripts:

- [Rev](#) for a comprehensive AI-generated version().
- [C-SPAN](#) for their full debate archive().

These sources should provide you with the complete dialogue from the debate, covering all the significant exchanges between the candidates.

clear memory

Memory has been cleared. How can I assist you next?

Transcript.txt  
Document

What's the largest size part of the attached transcript that you can handle. How many chunks do you need to break it up into

I can process parts of your transcript up to around 1,500 to 2,000 words at a time, depending on the complexity. Since your file is quite large, breaking it into chunks of approximately 1,500 words would allow me to handle and analyze each section efficiently.

If the entire transcript is 40,000 words, for example, this would mean splitting it into about 20-25 chunks. You can upload each chunk, and I'll assist with it in parts. Would you like me to help you break it up, or would you prefer to do so and send sections at a time?

How many words is what I uploaded

The uploaded transcript contains 18,043 words. If you'd like, I can help break it into smaller chunks for easier processing.

I want a script to reliable deduplication of speaker names (two words, e.g. "David Muir David Muir" that may or may not be separated by lines or spaces) and removal of timestamps (like "(00:39)").

Here's a Python script that should help you achieve both tasks: deduplicating speaker names (like "David Muir David Muir") and removing timestamps (such as "(00:39)"). It ensures that names are deduplicated even if they are separated by spaces, new lines, or punctuation, and it also removes timestamps reliably.

```
python
```

```
import re

def deduplicate_speaker_names(text):
    # Regular expression pattern to match speaker names duplicated consecutively
    name_pattern = r'(\b\w+\s\w+\b)[ \n]*\1'
    deduplicated_text = re.sub(name_pattern, r'\1', text)

    return deduplicated_text
```

```
def remove_timestamps(text):
    # Regular expression pattern to match timestamps like (00:39) or (1:02:15)
    timestamp_pattern = r'\(\d{1,2}:\d{2}(?:\d{2})?\)'
    text_without_timestamps = re.sub(timestamp_pattern, '', text)

    return text_without_timestamps

def process_transcript(text):
    # Deduplicate speaker names
    deduplicated_text = deduplicate_speaker_names(text)

    # Remove timestamps
    cleaned_text = remove_timestamps(deduplicated_text)

    return cleaned_text

# Example usage
with open('Transcript.txt', 'r') as file:
    transcript = file.read()

processed_transcript = process_transcript(transcript)

# Save the cleaned transcript to a new file
with open('Processed_Transcript.txt', 'w') as output_file:
    output_file.write(processed_transcript)

print("Processing complete. The cleaned transcript has been saved to 'Processed_Transcript.txt'.")
```

## Key Features:

- 1. Speaker Deduplication:** This script finds and removes duplicate occurrences of two-word speaker names that are either separated by spaces or new lines.
- 2. Timestamp Removal:** It detects timestamps like `(00:39)` or `(1:02:15)` and removes them from the text.

You can run this script on your transcript file, and it will output a cleaned version saved as `Processed\_Transcript.txt`. Let me know if you need any modifications!

I want a script to reliable deduplication of speaker names (two words, e.g. "David Muir David Muir" that may or may not be separated by lines or spaces) and removal of timestamps (like "(00:39)"). It should take commandline parameters for input and output files.

Here's a Python script that meets your requirements. It accepts command-line parameters for input and output files, removes duplicated speaker names (even if separated by lines or spaces), and removes timestamps.

```
python
```

```
import re
import argparse
```

```

def deduplicate_speaker_names(text):
    # Regular expression pattern to match speaker names duplicated consecutively
    # Handles cases where there might be spaces or new lines between duplicates
    name_pattern = r'(\b\w+\s\w+\b)[ \n]*\1'
    deduplicated_text = re.sub(name_pattern, r'\1', text)

    return deduplicated_text

def remove_timestamps(text):
    # Regular expression pattern to match timestamps like (00:39) or (1:02:15)
    timestamp_pattern = r'\((\d{1,2}:\d{2})(?::\d{2})?\)'
    text_without_timestamps = re.sub(timestamp_pattern, '', text)

    return text_without_timestamps

def process_transcript(input_file, output_file):
    # Read the input file
    with open(input_file, 'r') as file:
        transcript = file.read()

    # Deduplicate speaker names
    deduplicated_text = deduplicate_speaker_names(transcript)

    # Remove timestamps
    cleaned_text = remove_timestamps(deduplicated_text)

    # Write the cleaned text to the output file
    with open(output_file, 'w') as file:
        file.write(cleaned_text)

    print(f"Processing complete. The cleaned transcript has been saved to '{output_file}'.")

if __name__ == "__main__":
    # Setup command-line argument parsing
    parser = argparse.ArgumentParser(description="Deduplicate speaker names and remove timestamps from a transcript.")
    parser.add_argument("input_file", help="The path to the input transcript file.")
    parser.add_argument("output_file", help="The path to save the processed transcript.")

    args = parser.parse_args()

    # Process the transcript
    process_transcript(args.input_file, args.output_file)

```

## How It Works:

- 1. Speaker Deduplication:** The `deduplicate_speaker_names` function uses a regex to identify two-word speaker names that are repeated consecutively, even if separated by spaces or new lines, and reduces them to a single occurrence.
- 2. Timestamp Removal:** The `remove_timestamps` function identifies timestamps formatted like `(00:39)` or `(1:02:15)` and removes them from the text.
- 3. Command-line Interface:**
  - The script takes two arguments: `input_file` and `output_file`. These parameters specify the input transcript file and the file where the processed transcript will be saved.

## Usage:

You can run this script from the command line as follows:

bash

```
python process_transcript.py input_transcript.txt output_transcript.txt
```

Where `input_transcript.txt` is your original transcript file, and `output_transcript.txt` is the file where the cleaned transcript will be saved.

Let me know if you need any adjustments!

Additionally it should remove whitespace around a colon ":" and ensure that the text that may be on the next line immediately follows the colon. For example: "David Muir :

Welcome to you both. It's wonderful to have you. It's an honor to have you both here tonight.  
" becomes "David Muir: Welcome to you both. It's wonderful to have you. It's an honor to have you both here tonight."

Here's the updated Python script that adds functionality to remove any whitespace around a colon and ensures that text on the next line (if it immediately follows the colon) is moved to the same line:

python

```
import re
import argparse

def deduplicate_speaker_names(text):
    # Regular expression pattern to match speaker names duplicated consecutively
    # Handles cases where there might be spaces or new lines between duplicates
    name_pattern = r'(\b\w+\s\w+\b)[ \n]*\1'
    deduplicated_text = re.sub(name_pattern, r'\1', text)
    return deduplicated_text

def remove_timestamps(text):
    # Regular expression pattern to match timestamps like (00:39) or (1:02:15)
    timestamp_pattern = r'\((\d{1,2}:\d{2})(?::\d{2})?\)'
    text_without_timestamps = re.sub(timestamp_pattern, '', text)
    return text_without_timestamps

def clean_colons_and_whitespace(text):
    # Remove any spaces around colons and ensure the text that may be on the next line
    # follows the colon immediately.

    # Step 1: Remove whitespace around colons
    text = re.sub(r'\s*:\s*', ': ', text)

    # Step 2: Bring up the text following a colon that might be on a new line
    text = re.sub(r':\s*\n\s*', ': ', text)

    return text

def process_transcript(input_file, output_file):
    # Read the input file
    with open(input_file, 'r') as file:
        transcript = file.read()
```

```

# Deduplicate speaker names
deduplicated_text = deduplicate_speaker_names(transcript)

# Remove timestamps
cleaned_text = remove_timestamps(deduplicated_text)

# Clean colons and fix whitespace issues
final_text = clean_colons_and_whitespace(cleaned_text)

# Write the cleaned text to the output file
with open(output_file, 'w') as file:
    file.write(final_text)

print(f"Processing complete. The cleaned transcript has been saved to
'{output_file}'.")

if __name__ == "__main__":
    # Setup command-line argument parsing
    parser = argparse.ArgumentParser(description="Deduplicate speaker names, remove
timestamps, and clean up colon spacing in a transcript.")
    parser.add_argument("input_file", help="The path to the input transcript file.")
    parser.add_argument("output_file", help="The path to save the processed transcript.")

    args = parser.parse_args()

    # Process the transcript
    process_transcript(args.input_file, args.output_file)

```

## Key Updates:

### 1. Colon Whitespace Cleanup:

- The `clean_colons_and_whitespace` function ensures that any spaces around a colon are removed and that text after the colon (even if it is on the next line) is moved up to follow the colon immediately.
- `\s*:\s*` is used to remove any space before or after the colon, while `:\s*\n\s*` ensures the text immediately follows the colon even if it was on a new line.

## Usage:

You can run the script from the command line just like before:

```

bash

python process_transcript.py input_transcript.txt output_transcript.txt

```

Where `input_transcript.txt` is your original transcript file, and `output_transcript.txt` is the cleaned output file.

This version of the script will now:

1. Deduplicate speaker names.
2. Remove timestamps.
3. Clean colons and fix whitespace issues around colons.

 Let me know if you need further modifications!

Good. Now I want you to add the following functionality... generate an HTML file with readable dark text on a white background. Let Harris be blue, Trump be red, and the other speakers identified be other colors.

Here's the updated script that includes functionality to generate an HTML file with readable dark text on a white background. It assigns the following colors to the text of different speakers:

- **Kamala Harris:** Blue
- **Donald Trump:** Red
- **Other Speakers:** Different colors

This version will process the transcript and create an HTML file along with the cleaned text file.

python

```
import re
import argparse

# Define speaker colors
SPEAKER_COLORS = {
    'Kamala Harris': 'blue',
    'Donald Trump': 'red',
    'David Muir': 'green',
    'Lindsey Davis': 'purple',
    # Add other speaker names and their corresponding colors here if needed
}

def deduplicate_speaker_names(text):
    # Regular expression pattern to match speaker names duplicated consecutively
    name_pattern = r'(\b\w+\s\w+\b)[ \n]*\1'
    deduplicated_text = re.sub(name_pattern, r'\1', text)
    return deduplicated_text

def remove_timestamps(text):
    # Regular expression pattern to match timestamps like (00:39) or (1:02:15)
    timestamp_pattern = r'\((\d{1,2}:\d{2})(?::\d{2})?\)'
    text_without_timestamps = re.sub(timestamp_pattern, '', text)
    return text_without_timestamps

def clean_colons_and_whitespace(text):
    # Remove any spaces around colons and ensure the text that may be on the next line
    # follows the colon immediately.
    text = re.sub(r'\s*:\s*', ': ', text)
    text = re.sub(r':\s*\n\s*', ': ', text)
    return text

def generate_html(text, output_html_file):
    # Create the HTML structure with a white background and dark text
    html_content = """<html>
<head>
<style>
    body {
        background-color: white;
        color: black;
        font-family: Arial, sans-serif;
    }
    .kamala-harris {
        color: blue;
    }

```

```

        .donald-trump {
            color: red;
        }
        .david-muir {
            color: green;
        }
        .lindsey-davis {
            color: purple;
        }
        /* Add styles for other speakers here */
    </style>
</head>
<body>
    """

    # Add the colored speakers text
    for speaker, color_class in SPEAKER_COLORS.items():
        # Use regex to find speaker name followed by a colon and apply the corresponding
        color class
        pattern = rf"({speaker}):"
        replacement = rf'<span class="{color_class.lower().replace(" ", "-")}">\1:</span>'
        text = re.sub(pattern, replacement, text)

    # Add the processed text into the body
    html_content += text
    html_content += "</body>\n</html>"

    # Write the HTML content to the output file
    with open(output_html_file, 'w') as file:
        file.write(html_content)

    print(f"HTML file has been generated and saved to '{output_html_file}'.")

def process_transcript(input_file, output_file, output_html_file):
    # Read the input file
    with open(input_file, 'r') as file:
        transcript = file.read()

    # Deduplicate speaker names
    deduplicated_text = deduplicate_speaker_names(transcript)

    # Remove timestamps
    cleaned_text = remove_timestamps(deduplicated_text)

    # Clean colons and fix whitespace issues
    final_text = clean_colons_and_whitespace(cleaned_text)

    # Write the cleaned text to the output file
    with open(output_file, 'w') as file:
        file.write(final_text)

    print(f"Processing complete. The cleaned transcript has been saved to
    '{output_file}'.")

    # Generate the HTML file with colored speakers
    generate_html(final_text, output_html_file)

if __name__ == "__main__":
    # Setup command-line argument parsing
    parser = argparse.ArgumentParser(description="Deduplicate speaker names, remove
    timestamps, clean up colons, and generate an HTML file with colored speakers.")
    parser.add_argument("input_file", help="The path to the input transcript file.")
    parser.add_argument("output_file", help="The path to save the processed transcript.")
    parser.add_argument("output_html_file", help="The path to save the generated HTML
    file.")

    args = parser.parse_args()

    # Process the transcript and generate HTML
    process_transcript(args.input_file, args.output_file, args.output_html_file)

```

## Key Features:

1. **Speaker Deduplication:** The script deduplicates consecutive occurrences of two-word speaker names.
2. **Timestamp Removal:** Removes timestamps formatted like `(00:39)` or `(1:02:15)`.
3. **Colon Cleanup:** Fixes whitespace around colons and ensures that text after the colon is placed on the same line.
4. **HTML Generation:** Generates an HTML file with dark text on a white background. The speakers are color-coded:
  - **Kamala Harris:** Blue
  - **Donald Trump:** Red
  - **David Muir:** Green
  - **Lindsey Davis:** Purple
  - You can add more speakers and their colors as needed.

## Usage:

You can run the script from the command line with the following command:

```
bash
```

```
python process_transcript.py input_transcript.txt output_transcript.txt  
output_transcript.html
```

Where:

- `input\_transcript.txt` is the original transcript file.
- `output\_transcript.txt` is the cleaned text file.
- `output\_transcript.html` is the generated HTML file with colored speaker text.

Let me know if you need any further customizations!

the output transcript.html is not showing html

It looks like the issue might be due to the lack of proper handling of line breaks and formatting in the HTML output. Let's update the script to properly handle line breaks (`\n`), paragraphs, and other necessary HTML tags for better readability.

Here's the revised script that ensures the HTML is rendered correctly with line breaks and speaker formatting:

python

```

import re
import argparse

# Define speaker colors
SPEAKER_COLORS = {
    'Kamala Harris': 'blue',
    'Donald Trump': 'red',
    'David Muir': 'green',
    'Lindsey Davis': 'purple',
    # Add other speaker names and their corresponding colors here if needed
}

def deduplicate_speaker_names(text):
    # Regular expression pattern to match speaker names duplicated consecutively
    name_pattern = r'(\b\w+\s\w+\b)[ \n]*\1'
    deduplicated_text = re.sub(name_pattern, r'\1', text)
    return deduplicated_text

def remove_timestamps(text):
    # Regular expression pattern to match timestamps like (00:39) or (1:02:15)
    timestamp_pattern = r'\((\d{1,2}:\d{2}(:\d{2})?)\)'
    text_without_timestamps = re.sub(timestamp_pattern, '', text)
    return text_without_timestamps

def clean_colons_and_whitespace(text):
    # Remove any spaces around colons and ensure the text that may be on the next line
    # follows the colon immediately.
    text = re.sub(r'\s*:\s*', ': ', text)
    text = re.sub(r':\s*\n\s*', ': ', text)
    return text

def generate_html(text, output_html_file):
    # Create the HTML structure with a white background and dark text
    html_content = """<html>
<head>
<style>
    body {
        background-color: white;
        color: black;
        font-family: Arial, sans-serif;
        line-height: 1.6;
    }
    .kamala-harris {
        color: blue;
    }
    .donald-trump {
        color: red;
    }
    .david-muir {
        color: green;
    }
    .lindsey-davis {
        color: purple;
    }
    /* Add styles for other speakers here */
</style>
</head>
<body>
"""

    # Add the colored speakers text with proper paragraph handling
    for speaker, color_class in SPEAKER_COLORS.items():
        # Use regex to find speaker name followed by a colon and apply the corresponding
        # color class
        pattern = rf"({speaker}):"
        replacement = rf'<span class="{color_class.lower().replace(" ", "-")}">\1:</span>'
        text = re.sub(pattern, replacement, text)

```

```

# Replace new lines with <br> for HTML readability
text = text.replace("\n", "<br>\n")

# Add the processed text into the body
html_content += text
html_content += "</body>\n</html>"

# Write the HTML content to the output file
with open(output_html_file, 'w') as file:
    file.write(html_content)

print(f"HTML file has been generated and saved to '{output_html_file}'.")

def process_transcript(input_file, output_file, output_html_file):
    # Read the input file
    with open(input_file, 'r') as file:
        transcript = file.read()

    # Deduplicate speaker names
    deduplicated_text = deduplicate_speaker_names(transcript)

    # Remove timestamps
    cleaned_text = remove_timestamps(deduplicated_text)

    # Clean colons and fix whitespace issues
    final_text = clean_colons_and_whitespace(cleaned_text)

    # Write the cleaned text to the output file
    with open(output_file, 'w') as file:
        file.write(final_text)

    print(f"Processing complete. The cleaned transcript has been saved to '{output_file}'.")

    # Generate the HTML file with colored speakers
    generate_html(final_text, output_html_file)

if __name__ == "__main__":
    # Setup command-line argument parsing
    parser = argparse.ArgumentParser(description="Deduplicate speaker names, remove timestamps, clean up colons, and generate an HTML file with colored speakers.")
    parser.add_argument("input_file", help="The path to the input transcript file.")
    parser.add_argument("output_file", help="The path to save the processed transcript.")
    parser.add_argument("output_html_file", help="The path to save the generated HTML file.")

    args = parser.parse_args()

    # Process the transcript and generate HTML
    process_transcript(args.input_file, args.output_file, args.output_html_file)

```

## Key Updates:

- Line Breaks:** The new lines (`\n`) in the transcript are now replaced with `  
` tags, ensuring the text in the HTML file displays properly with line breaks.
- HTML Structure:** The text is wrapped in a proper HTML structure with `style` definitions for the background, font, and speaker colors.
- Speaker Highlighting:** The speakers are highlighted with the assigned colors (blue for Kamala Harris, red for Donald Trump, etc.).

## Usage:

Run the script with the following command:

```
bash

python process_transcript.py input_transcript.txt output_transcript.txt
output_transcript.html
```

This will:

1. Process the transcript, deduplicate speaker names, remove timestamps, and fix whitespace issues.
2. Generate an HTML file (`output_transcript.html`) that formats the text with colors for speakers and maintains readability with line breaks.

Now, the generated HTML file should display correctly in a browser with the expected formatting. Let me know if you encounter any issues or need further customization!

**transcript.html**  
File

Please review the attached html and explain why it isn't being generated in color text.

Upon reviewing the HTML file you uploaded, I noticed an issue with the color class names being improperly used. Specifically, the speaker names such as "David Muir," "Kamala Harris," and "Donald Trump" are correctly wrapped in `<span>` elements, but the class names like `"green"`, `"blue"`, and `"red"` are directly used as the class names for the speakers, rather than the intended classes from your CSS.

To fix this:

## Problem:

In the `<style>` block, you have class names such as `.kamala-harris`, `.donald-trump`, etc., while in the HTML body, you're using `"blue"`, `"red"`, and `"green"` as the classes, which do not correspond to your CSS rules.

## Solution:

1. **Ensure the class names in your `<span>` elements match the classes defined in your CSS.**
  - For example, instead of `<span class="blue">Kamala Harris:</span>`, it should be `<span class="kamala-harris">Kamala Harris:</span>`.
  - Instead of `<span class="red">Donald Trump:</span>`, it should be `<span class="donald-trump">Donald Trump:</span>`.

Here's an example of the corrected HTML code:

html

```
<html>
<head>
  <style>
    body {
      background-color: white;
      color: black;
      font-family: Arial, sans-serif;
      line-height: 1.6;
    }
    .kamala-harris {
      color: blue;
    }
    .donald-trump {
      color: red;
    }
    .david-muir {
      color: green;
    }
    .lindsey-davis {
      color: purple;
    }
  </style>
</head>
<body>
  <span class="david-muir">David Muir:</span> Tonight, the high-stakes showdown here in
  Philadelphia...
  <br>
  <span class="lindsey-davis">Lindsey Davis:</span> A historic race for president upended...
  <br>
  <span class="kamala-harris">Kamala Harris:</span> Together, we will chart a new way
  forward...
  <br>
  <span class="donald-trump">Donald Trump:</span> We will soon be a great nation again...
</body>
</html>
```

This will ensure the speaker names are correctly styled according to the CSS.

## Steps to Implement:

1. Update the class names in the `` elements to match the corresponding CSS styles (`kamala-harris`, `donald-trump`, `david-muir`, etc.).
2. Ensure that all speaker references use the appropriate classes in the HTML.

Once you make this change, the colors for each speaker should display correctly in the HTML file when opened in a browser. Let me know if you need further assistance!

Fix the python code to do this

Here is the updated Python code that generates an HTML file with proper class names for the speakers. The class names in the `` elements will now match the corresponding styles in the CSS (e.g., `.kamala-harris`, `.donald-trump`).

python

```
import re
import argparse

# Define speaker colors with proper CSS class names
SPEAKER_COLORS = {
    'Kamala Harris': 'kamala-harris',
    'Donald Trump': 'donald-trump',
    'David Muir': 'david-muir',
    'Lindsey Davis': 'lindsey-davis',
    # Add other speaker names and their corresponding classes here if needed
}

def deduplicate_speaker_names(text):
    # Regular expression pattern to match speaker names duplicated consecutively
    name_pattern = r'(\b\w+\s\w+\b)[ \n]*\1'
    deduplicated_text = re.sub(name_pattern, r'\1', text)
    return deduplicated_text

def remove_timestamps(text):
    # Regular expression pattern to match timestamps like (00:39) or (1:02:15)
    timestamp_pattern = r'\((\d{1,2}:\d{2})(?::\d{2})?\)'
    text_without_timestamps = re.sub(timestamp_pattern, '', text)
    return text_without_timestamps

def clean_colons_and_whitespace(text):
    # Remove any spaces around colons and ensure the text that may be on the next line
    # follows the colon immediately.
    text = re.sub(r'\s*:\s*', ': ', text)
    text = re.sub(r':\s*\n\s*', ': ', text)
    return text

def generate_html(text, output_html_file):
    # Create the HTML structure with a white background and dark text
    html_content = """<html>
<head>
    <style>
        body {
            background-color: white;
            color: black;
            font-family: Arial, sans-serif;
            line-height: 1.6;
        }
        .kamala-harris {

    file.")

    args = parser.parse_args()

    # Process the transcript and generate HTML
    process_transcript(args.input_file, args.output_file, args.output_html_file)

```

## Key Changes:

### 1. CSS Class Names in the HTML:

- In the `generate\_html` function, we now replace the speaker names with proper class names (e.g., `kamala-harris` instead of `blue`).
- This ensures that the class names in the `` elements match the CSS classes defined in the `

## 2. Updated Regex Replacement:

- The regex replacement in the ``generate_html`` function uses the speaker's name (e.g., "Kamala Harris") to find the occurrence of the name followed by a colon, and it wraps it with the correct class name.

## Usage:

Run the script using the following command:

```
bash
```

```
python process_transcript.py input_transcript.txt output_transcript.txt
output_transcript.html
```

This will:

1. Process the transcript, deduplicate speaker names, remove timestamps, and clean up the colons.
2. Generate an HTML file (``output_transcript.html``) that formats the text with the correct CSS class names for each speaker.

Let me know if you have any further questions!

Better. Make the speaker name BOLD, and the text (what follows) the same color, but not bold. Additionally there is a speaker named "Speaker 1" in the text file so they get their own color too and the rules apply.

Here is an updated version of the script that makes the speaker names bold, ensures the following text remains the same color but not bold, and adds handling for "Speaker 1" with its own color. The HTML will now look like:

- **Bold speaker names** (e.g., **Kamala Harris:**) followed by text in the same color but not bold.
- Added handling for "Speaker 1" with a unique color.

## Updated Python Script:

```
python
```

```
import re
import argparse

# Define speaker colors with proper CSS class names
SPEAKER_COLORS = {
    'Kamala Harris': 'kamala-harris',
    'Donald Trump': 'donald-trump',
    'David Muir': 'david-muir',
    'Lindsey Davis': 'lindsey-davis',
```

```

'Speaker 1': 'speaker-1', # New speaker added with its own color
}

def deduplicate_speaker_names(text):
    # Regular expression pattern to match speaker names duplicated consecutively
    name_pattern = r'(\b\w+\s\w+\b)[ \n]*\1'
    deduplicated_text = re.sub(name_pattern, r'\1', text)
    return deduplicated_text

def remove_timestamps(text):
    # Regular expression pattern to match timestamps like (00:39) or (1:02:15)
    timestamp_pattern = r'\((\d{1,2}:\d{2}(\?:\d{2})?\)\)'
    text_without_timestamps = re.sub(timestamp_pattern, '', text)
    return text_without_timestamps

def clean_colons_and_whitespace(text):
    # Remove any spaces around colons and ensure the text that may be on the next line
    # follows the colon immediately.
    text = re.sub(r'\s*:\s*', ': ', text)
    text = re.sub(r':\s*\n\s*', ': ', text)
    return text

def generate_html(text, output_html_file):
    # Create the HTML structure with a white background and dark text
    html_content = """<html>
<head>
    <style>
        body {
            background-color: white;
            color: black;
            font-family: Arial, sans-serif;

    final_text = clean_colons_and_whitespace(cleaned_text)

    # Write the cleaned text to the output file
    with open(output_file, 'w') as file:
        file.write(final_text)

    print(f"Processing complete. The cleaned transcript has been saved to '{output_file}'.")

    # Generate the HTML file with colored speakers
    generate_html(final_text, output_html_file)

if __name__ == "__main__":
    # Setup command-line argument parsing
    parser = argparse.ArgumentParser(description="Deduplicate speaker names, remove timestamps, clean up colons, and generate an HTML file with colored speakers.")
    parser.add_argument("input_file", help="The path to the input transcript file.")
    parser.add_argument("output_file", help="The path to save the processed transcript.")
    parser.add_argument("output_html_file", help="The path to save the generated HTML file.")

    args = parser.parse_args()

    # Process the transcript and generate HTML
    process_transcript(args.input_file, args.output_file, args.output_html_file)

```

## Key Updates:

1. **Bold Speaker Names:** The speaker names (e.g., Kamala Harris, Donald Trump) are now wrapped in a `**` tag to make them bold.**
2. **Colored Text After Speaker Names:** The text that follows the speaker names remains the same color as the speaker but is not bold. This is done by opening a `` tag after the speaker's name and closing it at the end of each line.
3. **Added "Speaker 1" Handling:** "Speaker 1" has been added with its own color (orange in this case). You can modify the color as needed by adjusting the CSS in the `

```
bash
```

```
python process_transcript.py input_transcript.txt output_transcript.txt  
output_transcript.html
```

This will:

1. Clean up the transcript (deduplicate names, remove timestamps, and fix colons).
2. Generate an HTML file (`output_transcript.html`) where speaker names are bold and the following text is the same color but not bold.
